Stablecoin Overview

This document describes Veem's stablecoin payments capability — the rationale, core capabilities and implementation steps.

About Veem

Veem is a global business payments platform that enables partners and their end users to send and receive payments across fiat and digital asset rails. This document covers Veem's stablecoin payment capability, delivered through a phased integration with a regulated stablecoin infrastructure provider.

Overview

Veem is extending its payment infrastructure to support on-chain stablecoin settlement, beginning with USDC and USDT. The capability enables payers and beneficiaries to fund, send, and receive payments in both fiat and stablecoins — through the same platform, compliance framework, and audit infrastructure already in place.

Why Stablecoin

Traditional payment rails carry structural limitations — multi-day settlement windows, correspondent banking dependencies, and limited programmability — that stablecoin rails are designed to address. USDC and USDT settle on-chain in minutes, reach any wallet address globally, and support programmable money movement without the overhead of legacy clearing networks. For cross-border payments, especially, stablecoin is a better rail that costs a fraction of what correspondent banking charges.

Key advantages of stablecoin settlement:

- **Speed:** settles in minutes, 24/7 including weekends and holidays.
- **Global reach:** any wallet on a supported chain, no correspondent bank needed.
- **Lower cost:** flat network fees instead of wire fees and FX spread.
- **Audit trail:** every transaction is on-chain and immediately verifiable.

Businesses are already moving money this way. Veem's advantage is that it brings stablecoin onto a regulated, compliant platform — something crypto-native tools can't offer. Demand for stablecoin payment infrastructure is increasing among technology-forward businesses, crypto-native companies, and cross-border marketplaces. Veem's capability is designed to serve this on demand payments while

maintaining the compliance and reliability standards partners expect from a regulated payment platform.

Account Issuance: Stablecoin Wallet - Coverage & Accounts Eligibility

Veem offers stablecoins wallets in USDT and USDC.

USDT and USDC Stablecoin Wallet : These wallets support receipt and holding of USDT and USDC, subject to country eligibility in the coverage matrix.

Availability: Veem can issue Stablecoin Wallets for account holders in 90+ countries. Stablecoin Wallets can be issued in Veem-supported countries mentioned in the coverage matrix. Eligibility (Consumer, Sole Prop, Business) is determined by the account holder's country and should always be validated against the Country Coverage Matrix before onboarding.

Wallet Address: Each wallet comes with a unique wallet address that can be used to send or receive fund Veem provisions and a unique wallet address for on-chain deposits that can be used by the customers to transact. The address is chain-specific and must be displayed together with the selected network to avoid mis-sends.

Commented [1]: Story:
1. Talk about Veem
2. Intro to Stablecoin and Stablecoin why it is important for the audience
3. Who can we service -- Coverage - what can we give them/product options
4. Ways to fund - on-Ramp of items in #3
5. Ways to drain- off-Ramp of items in #3
6. Bringing it all together
7. Additional considerations
8. Next Steps/Getting started

Commented [2]: Looks like one wallet - can have multiple addresses - each unique chain.

Commented [3]: I googled and this is what I found: Yes, one wallet address can sometimes support multiple chains—but usually only within the EVM family, and only when the provider/product explicitly supports it.

No, you should not assume one address supports both EVM and non-EVM chains such as Solana.

Operationally, the safest UX is still to present deposits as chain-specific instructions unless your API/provider explicitly tells you the address is unified for those chains.

For your example:

Base + Ethereum: often yes, potentially same address under unified EVM addressing.

Solana + Base: generally no, do not assume same address.

Currencies: USDT and USDC

How it works: A Stablecoin Wallet is issued to the account holder after onboarding and eligibility checks are completed. Once issued, the wallet can receive supported stablecoins directly on supported blockchain rails. Funds received into the wallet are credited to the customer's stablecoin balance and can then be held, transferred, or off-ramped through supported payout options. Each issued wallet includes chain-specific deposit addresses that partners can surface in-product for collections and payouts.

Use case: Veem's stablecoin wallet is best suited for customers who want to receive, hold, and move funds using stablecoins. Typical use cases include: wallet-based collections, cross-border treasury movement, and stablecoin-native payout flows.

QR Code: Partners can render the issued deposit address as a QR code (e.g., chain URI formats where supported) to simplify funding. The QR should encode both the address and the network context when supported by the wallet app.

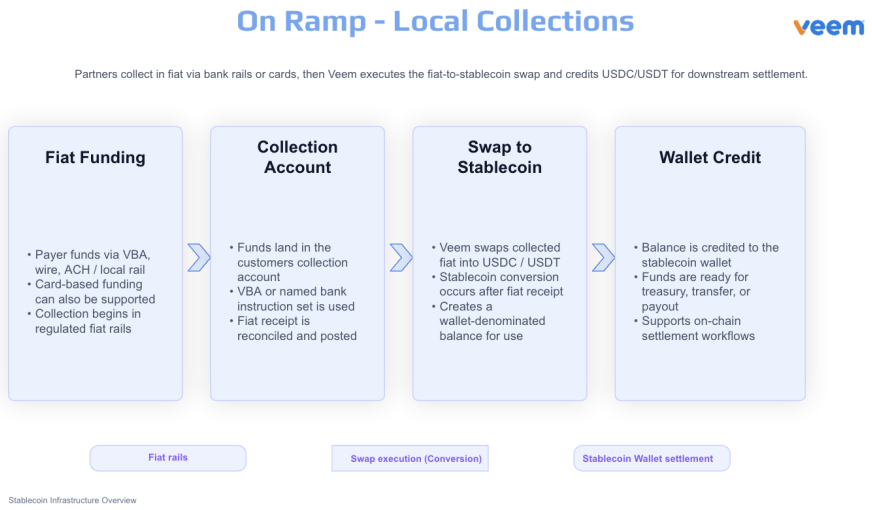
Individuals (Consumers): Supported for consumer users, where enabled by the partner program and KYC requirements.

Businesses & Sole Proprietorships: Supported for business entities and sole proprietors, subject to KYB verification.

HOW A STABLECOIN COLLECTION WORKS

On-Ramp (Collections) - Stablecoin Wallet

Customers fund in fiat using local collection rails such as VBAs, wire transfers, or card-based funding, where supported. Veem then converts, or swaps, the incoming fiat into USDC or USDT, creating a stablecoin balance without exposing the customer to unnecessary FX or crypto volatility during collection. This on-ramp flow combines familiar payment acceptance methods with faster blockchain-based value movement. It is best suited for customers who want to collect in fiat and settle into stablecoins.



Each stablecoin wallet comes with a unique stablecoin wallet address for collections and payouts. Account holders can share the wallet address with their customers to collect payments globally.

- **Supported stablecoins:** USDC and USDT.
- **Supported chains:** Ethereum, Base, Solana, Tron, HyperEVM. Additional EVM chains can be added quickly.
- **Swapping**: FIAT to Stablecoin swap is supported. Accept, Convert/Off ramp to various FIATs.
- **Wallet setup:** USDC and USDT wallets are provisioned via the Veem API.
- **Local collections can be accepted in** US, EU, MX, BR backed via Stablecoins USDC & USDT wallets.
- **Supported funding methods:** - Swift Wires, Credit Card, Debit Card: ACH and Wire (USD), SEPA IBAN (EUR), SPEI (MXN), PIX (BRL), Faster Payments (GBP)*. [Check the country coverage map for details]
- **Compliance:** KYC for individuals, KYB for businesses & sole props.

USE CASE 1 (STABLECOIN WALLET): *A Japanese marketplace merchant invoices an African buyer for $50,000. The buyer sends USDC to a Veem-generated deposit address. Veem detects on-chain settlement, credits the marketplace USDC wallet, and auto-closes the invoice — all within minutes. The merchants on the Japanese market place can get settled in JPY or USD*

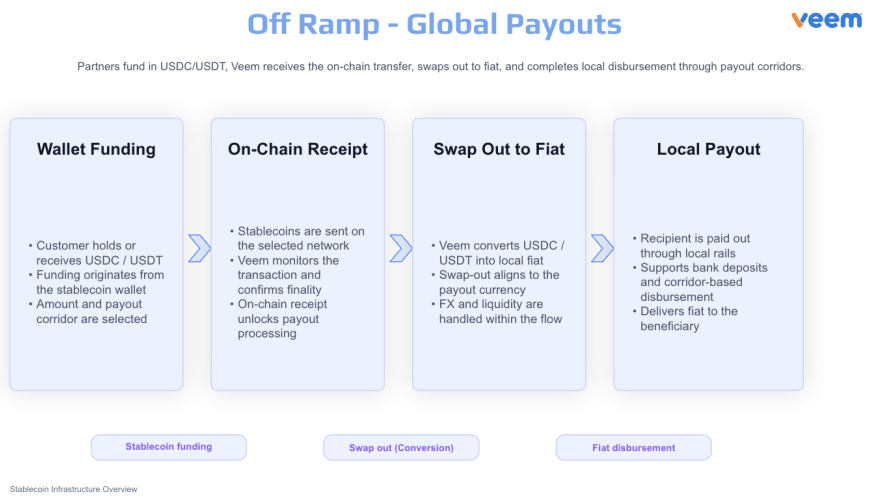
USE CASE 2 (VIRTUAL BANK ACCOUNT): *A U.S. software company invoices a customer in Germany. The German customer pays via SEPA IBAN into the company's Veem EUR stablecoin virtual account. Funds arrive within minutes— no SWIFT fees, no FX spread. The US software company can receive funds in USD, or in stablecoins.*

HOW A STABLECOIN DISBURSEMENT WORKS

Off-Ramp (Disbursement)

Customers initiate disbursements from a USDC or USDT balance and Veem manages the swap out into fiat where local payout is required. Funds can then be sent through supported payout corridors to the beneficiary's bank account or local rail. This off-ramp model allows customers to use stablecoins as the settlement layer while still delivering fiat to end recipients. It is ideal for treasury, supplier payments, and cross-border payouts where recipients prefer traditional bank settlement.

For customers paying a beneficiary in fiat, Veem converts the stablecoin balance and routes it through the most cost-effective corridor. No manual conversion needed.



- **Supported offramps:** - Local Bank Accounts, Push to Cards, Stablecoin wallets [Check the country coverage map for details].
- **Swapping**: Stablecoin to FIAT swap is supported. Accept, Convert/Off ramp from USDC/USDT stablecoins.
- **Self off-ramp:** customer withdrawing to their own bank account is treated as a wallet-to-bank withdrawal.
- **Supported stablecoins:** USDC and USDT.
- **Supported chains:** Ethereum, Base, Solana, Tron, HyperEVM.

- **Supported payout currencies for fiat off-ramp:** 110 countries and 80+ currencies
- **Supported payout rails:** ACH and Wire (USD), Push to Cards (VIsa / MC), Swift wires, and Local bank transfers as well as virtual prepaid cards (in some markets)

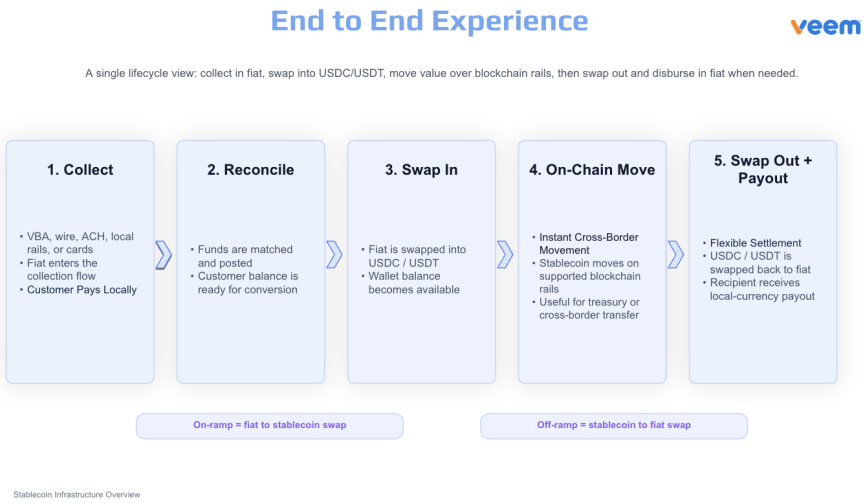
EXAMPLE

A payroll platform pays 50 remote contractors across 20 countries. Contractors with a crypto wallet receive USDC directly in minutes. Contractors who prefer their bank account receive the equivalent in fiat via ACH, SEPA, or the applicable local rail — all from the same Veem API call.

Summary

Commented [4]: We can have an additional information section and cover what is not covered above - but there should not be any duplication of information.

Veem enables a full stablecoin payments journey across both collection and disbursement flows. Customers can “on-ramp” from fiat into USDC/USDT, hold or move stablecoins over blockchain rails, and "off-ramp” back into fiat at the point of payout. This creates a flexible end-to-end experience that combines local payment acceptance, on-chain settlement, and global disbursement in a single flow. The result is a simpler cross-border payments model with better speed, transparency, and settlement flexibility.



Integration Options

Stablecoin capabilities are available through the below access path.

- **API gateway (gateway-domain):** public-facing REST API for partner integrations.

The provider integration uses REST APIs with secure credentials and adheres to the provider's protocol specifications, namespace conventions, and event webhook schema.

Getting Started

Veem's stablecoin infrastructure lets your business send and receive real-time, cross-border payments on USDT & USDC rails — with modular KYC/KYB compliance, virtual accounts, and automated transfers ready to go from day one.

Here's what our Stablecoin capabilities gets you:

- Customer onboarding & KYC/KYB verification
- Virtual account provisioning
- Fiat-to-stablecoin transfers
- Saved payment templates — configure once, reuse anytime
- Real-time event notifications via webhooks
- Full public API access with live status monitoring

Sandbox-ready. Before we go live, we'll walk through a full QA sign-off together — covering your onboarding flow, account funding, and your first fiat-to-stablecoin transfer in a safe test environment. No surprises on launch day.

Ready to get started? Talk to our Veem Sales team. Let's set up your sandbox credentials and kick off the integration.
